What is a PV DC arc fault?

Most PV DC arc faults are series arcs across a high-resistance gap. Parallel arcs occur between conductors or to ground. Series arcs often show wideband current noise, typically concentrated between 1 kHz and 100 kHz, superimposed on the DC string current. Arc power can range from a few hundred watts into the kilowatt range in high-current strings.

How does arcing affect a PV array?

The arc damages conductors, increases contact resistance, and can reignite intermittently. AC zero crossings self-extinguish many arcs. DC has no zero crossing, so arcs can persist. PV arrays also produce limited short-circuit current. That narrows the detectable current swing during arcing compared with grid faults.

What is arc fault in solar systems?

What is Arc Fault in Solar Systems and how to deal with it? Check out some of the other great posts in this blog. An arc fault in a solar system occurs when an electrical current jumps across a gap between two conductive surfaces, creating a brief but intense burst of heat and light.

Can arc detection be used in high-voltage applications?

Figure 9: Arc detection can be added into a variety of high-voltage applications to mitigate the risks associated with high voltages. In an electrical vehicle, for example, arc detection can monitor the high-voltage DC busses between the primary batteries and inverter stages that are known to be a common cause of catastrophic vehicle fires.
