

Does a wind-powered thermal energy system convert wind power into heat?

The focus of this research is a techno-economic assessment of a wind-powered thermal energy system (WTES), which directly converts wind power into heat at the generation site and stores this heat in thermal energy storage for later use.

How can wind energy be used for heating?

WTES is another option to use wind energy for heating. This system converts wind power into heat at generation sites, and the generated heat can be transferred to heat users through transmission or transport systems. A WTES has a minimal number of energy conversion steps to convert wind power into heat.

What is a wind-powered heating system?

Wind-powered heating systems that convert and store wind power as heat and convert the stored heat into electricity were issued in two patents in 2012. In this type of system, a liquid is heated by wind-driven hydrodynamic retarders and is stored in liquid tanks.

How does a wind power system work?

In principle, WTES has a minimal number of energy conversion steps to convert wind power into heat, and the investment cost and energy loss of the system are therefore lower than those of other systems, such as a conventional wind power system that converts wind power to electricity and then generates heat by electric heaters.
